Photomasks and Pellicles

Only three firms in the world make the blank plates for the masks used to print the finest layers of leading-edge chips. Japan's AGC and Hoya are two of them.

IN PLAIN TERMS

A photomask is the stencil that lithography prints from, at least one for each layer of a chip[1]. The same mask prints its layer on wafer after wafer, so one mask shapes millions of chips. The most complicated layers are printed with extreme ultraviolet (EUV) light, and the rest can often be printed with deep ultraviolet light shone through a quartz plate. No glass lets EUV light through, so the mask for those layers is a mirror. The mirror is built up from about forty pairs of thin layers, and the light bounces off it. A dark pattern drawn on top of the mirror soaks up the light wherever no line should print. Any speck of dust on the mask repeats on every wafer it prints. So a thin membrane on a frame, called a pellicle, sits just above the mask and catches dust where it is too far out of focus to print. Japan's AGC and Hoya are two of the three firms that make those mirrors.

IN SHORT

On CSET's count from TechInsights data, Austria's IMS Nanofabrication held 46.6 percent of the 2025 world market for electron-beam mask writers, which draw the pattern onto a mask[2]. Hoya says its share of the mask blank market is exceptionally high[3].

SemiAnalysis put a full set of masks for a leading-edge chip at $40 million in May 2026[4]. In July 2022 it wrote that more companies will lack the volume to spread the fixed cost of mask sets[5]. On 8 September 2026 ASML and TSMC announced a plan to move from 6-inch to 12-inch masks[6]. They expect the change to raise fab productivity and lower chipmaking costs[6].

CHOKEPOINT CARD

CONCENTRATION	SUBSTITUTABILITY	PRICE OR MARKET SIZE
Extreme Three or fewer firms could supply this stage today, or one firm holds more than half of it.	**Hard** AGC said in December 2024 that only three firms supply the blank plates for EUV masks[7].	**$40M** for a leading-edge mask set, SemiAnalysis's May 2026 figure[4]. In July 2022 it put a 7 nm set above $10M[5]

WHO LEADS	JP	**AGC** Ranks itself No.2 worldwide in EUV mask blanks on its own fiscal 2026 estimates[8]
	JP	**Hoya** Said in its 2026 report that its share of mask blanks is exceptionally high[3]
	JP	**Lasertec** Launched the world's first tool that inspects patterned EUV masks at the scanner's own wavelength in 2019[9]
	AT	**IMS Nanofabrication** CSET puts its 2025 share of the market for all electron-beam mask writers at 46.6%, using TechInsights data[2]
	US	**Photronics** $849.3M of revenue in fiscal 2025[10]
WHERE IT IS MADE	JP	**Japan** Mask blanks (AGC, Hoya), DUV blanks (Shin-Etsu), inspection (Lasertec), writers (NuFlare), pellicles (Mitsui Chemicals)
	AT	**Austria** IMS Nanofabrication multi-beam mask writers
	DE	**Germany** Zeiss mask checking in EUV light (AIMS EUV) and mask repair
	US	**United States** Photronics merchant mask shops, KLA inspection
	TW	**Taiwan** TSMC, which held 10% of IMS at the end of 2024
WHY SUBSTITUTION IS SLOW		AGC says it spent more than a decade meeting the blank's requirements, and mass production began only in 2017[7]. Germany's Zeiss calls its AIMS the only system that tests how a mask will print under conditions equivalent to the scanner's[11].

WHERE CHINA STANDS	WHERE THE US STANDS
As of 2026 SMIC runs two mask shops of its own in Shanghai[12]. No Chinese firm appears in CSET's 2025 market shares for electron-beam mask writers, the machines that draw the pattern onto a mask[2].	In December 2025 Photronics called itself a leading worldwide maker of photomasks[10]. As of 2026 KLA sells tools that inspect EUV and optical masks[13].

Each EUV layer of an AI accelerator is printed from a mask built on a blank plate. Only three companies worldwide supply those plates, and Japan's AGC is one of them[7]. Hoya, also Japanese, is another[3]. AGC says it is the only company in the world that takes an EUV blank all the way from the glass to the finished coating[14].

How it works

How a photomask prints its pattern

1. **The scanner.** A photomask is the stencil that lithography prints from, at least one for each layer of a chip. Inside the scanner, light bounces off the mask and carries its pattern down to the wafer.
2. **A mirror.** No glass lets extreme ultraviolet (EUV) light through. So the mask for EUV layers is a mirror, built up from about forty pairs of very thin layers laid on glass, and the light bounces off it.
3. **The pattern.** A dark pattern drawn on the mirror soaks up the light wherever no line should print. The light that bounces back carries the pattern of one layer.
4. **Wafer after wafer.** The same mask prints its layer on wafer after wafer, so one plate shapes millions of chips.
5. **One speck.** A speck of dust on the mask prints on every wafer, until someone finds it. So a thin membrane on a frame, called a pellicle, covers the mask's patterned side and catches dust where it is too far out of focus to print.

Simplified. The mask is drawn face down, as it sits in the scanner. The mirror layers and the dark pattern are drawn far thicker than they are, and the light's path through the scanner's mirrors is cut to one bounce.

ASML says a chip's most complicated layers are made on EUV machines, while the rest can often be printed on older deep ultraviolet machines[15]. A mask starts as a blank, a polished plate with no pattern on it yet. For deep ultraviolet the blank is a window of quartz carrying a light-blocking film such as molybdenum silicide, and Shin-Etsu is one maker of those blanks[16]. For EUV the blank is a mirror of about 40 molybdenum and silicon layer pairs, 7 nm to a pair, laid on glass[17]. A dark tantalum film on top, called the absorber, will carry the pattern[18].

The blank is coated with a sensitive film called resist. A mask writer then draws the design into the resist with electrons. A single-beam writer flashes one shape at a time, while NuFlare's multi-beam writer for the most advanced masks controls 260,000 beams at once[19].

15 See ASML's DUV lithography systems. ASML, accessed 9 September 2026. asml.com

19 EB Mask Writer. NuFlare Technology, accessed 9 September 2026. nuflare.co.jp

A wash removes the drawn resist. An etch then removes the blocking film or absorber wherever the resist is gone, and the rest of the resist is stripped. The plate now passes light, or reflects it, in the shape of one layer of the chip. On standard EUV scanners the pattern is drawn four times larger than it will print[20]. An inspection tool compares the plate to the design, and a repair tool fixes the stray defects it finds.

EUV masks bring problems of their own:

- **Mask 3D effects.** Light strikes the mirror at a slant, and the absorber has height, so its edges cast small shadows that distort the printed shape. Software has to correct for the shadows in advance.
- **Write precision.** Every edge of the absorber has to sit within a few nanometers of where the design says.
- **Particles.** Anything on the mirror prints on every wafer until someone finds it.

High-NA scanners, the newest EUV machines, print finer lines with larger mirrors. To keep masks at their usual size, their mirrors shrink the pattern four times in one direction and eight times in the other[20]. So each exposure covers half the area of a standard exposure, and a wafer takes twice as many exposures[20].

On 8 September 2026 ASML and TSMC announced a plan to move from the current 6-inch masks to 12-inch masks[6]. They expect the change to raise fab productivity, lower chipmaking costs and remove stitching constraints, the design limits that come from printing a large chip in two halves[6]. They aim to set up a 12-inch mask pilot line by 2031, so that High-NA scanners using 12-inch masks can enter advanced chip production by 2033[6].

Variants and trade-offs

Blanks

AGC says it spent more than a decade meeting the blank's requirements, which include near-zero thermal expansion, perfectly smooth and flat surfaces and no particle contamination[7]. It says mass production began only in 2017[7].

AGC publishes no market share figure for EUV blanks. In its data book, AGC ranks itself No.2 worldwide in EUV blanks, based on its own fiscal 2026 estimates[8]. Hoya says its share of the mask blank market is exceptionally high, and that customers may gradually start buying EUV blanks from more than one supplier[3].

In April 2023 AGC said its EUV blank capacity would grow by about 30 percent in 2025[14]. The growth would come from a line in Fukushima, a project that METI, Japan's industry ministry, selected under a program to

20 5 things you should know about High NA in EUV. ASML, 25 January 2024. asml.com

strengthen supply chains[14]. AGC also said it was aiming for more than ¥40 billion of sales in the business by 2025[14]. Its EUV blank sales grew 50 percent in 2023, AGC said in December 2024[7]. In February 2025 AGC reported that the sales reached ¥40 billion in 2024, a year ahead of the 2025 target[21].

The sales then declined in 2025 and were recovering in 2026, AGC said in June 2026[22]. In August 2026 AGC set out capacity expansions of 20 to 50 percent across EUV blanks, polishing slurry and lens materials for lithography tools[23]. It gave no separate figure for the blanks, and mass production on the added capacity is to begin in 2028[23].

Writers

An electron-beam writer draws the pattern into the resist on the blank. Multi-beam writers fire many beams at once, and Japan's NuFlare sells them for the 3 nm node[19].

In September 2023 Intel called Austria's IMS Nanofabrication the established industry leader in the multi-beam mask writing tools that advanced EUV requires[24]. Counting all electron-beam mask writers, CSET, a research center at Georgetown University, put IMS's share of a $994 million world market at 46.6 percent in 2025, using TechInsights data[2]. NuFlare had 39.2 percent and JEOL 14.2 percent, in the same CSET analysis of TechInsights data[2].

Intel agreed in September 2023 to sell roughly 10 percent of IMS to TSMC at a valuation of about $4.3 billion[24]. TSMC's subsidiary TSMC Development held that 10 percent at the end of 2024, at a fair value of $432.8 million in TSMC's accounts[25]. Intel sold a combined 32 percent of IMS in 2023 and still held the other 68 percent on 27 December 2025[26].

Inspection and repair

A mask defect cuts the number of good chips on every wafer that mask prints, so masks are checked as blanks, after patterning and again at the fab. Actinic inspection uses 13.5 nm light, the wavelength of EUV lithography[9]. In 2019 Lasertec launched the world's first actinic inspection system for patterned EUV masks, the ACTIS A150[9]. In October 2025 it launched the ACTIS A200HiT series, which it says triples the A150's inspection speed[9]. Lasertec reported net sales of JPY 230,485 million in the year to June 2026[27].

As of 2026 KLA's Teron systems for mask shops detect pattern and particle defects on both EUV and optical masks[13].

Zeiss makes AIMS EUV, which checks a mask in EUV light under the scanner's own imaging conditions to judge how a defect will affect printing[11]. Zeiss calls AIMS the only system that tests how a mask will print under conditions equivalent to the scanner's[11]. Zeiss says the tool can be extended to ASML's High-NA scanner, the EXE:5000[11]. Zeiss also sells electron-beam repair tools that work on EUV masks[28].

Pellicles

A pellicle is a thin membrane on a frame above the mask. Particles land on it, too far out of focus to print, and the pattern below stays clean.

In 2022 ASML described its most advanced EUV pellicle as a membrane 13 nanometers thick that can withstand up to 500 degrees Celsius in a high vacuum[29]. Every photon it absorbs is light that never reaches the wafer[29]. The light crosses it twice, on the way in and on the way back off the mirror, so absorption counts double. ASML released its first EUV pellicles in 2016 and calls the pellicle one of the breakthroughs that brought EUV lithography to high-volume manufacturing[29].

Carbon nanotube membranes are the next step, aimed at next-generation High-NA, high-output EUV scanners[30]. In 2020 imec, a Belgian chip research center, mounted them on masks and exposed them in an ASML NXE:3300 scanner[31]. The membranes passed up to 97 percent of the light in a single crossing, and imec found their effect on imaging low and correctable[31].

Mitsui Chemicals began commercial production of silicon-based EUV pellicles under an ASML license in 2021[30]. In 2024 it said it would build a carbon nanotube membrane plant at Iwakuni-Ohtake, tentatively due to finish in December 2025[30]. In December 2025 Mitsui Chemicals said the plant was scheduled for completion in its fiscal 2025, in line with its initial plan[32]. The membranes are designed to pass 92 percent or more of the light and to withstand exposure power above 1 kW[30].

Cost and design economics

In July 2022 SemiAnalysis put mask sets above $1 million at 28 nm and above $10 million at 7 nm[5]. It expected 3 nm mask sets to reach the $40 million range[5]. Its May 2026 primer still puts a leading-edge mask set at $40 million[4]. The same primer puts a single respin, remaking a chip after a design flaw, at $50 million to $100 million at leading-edge nodes[4].

Mask costs restrict which firms can use a node. SemiAnalysis wrote that at 5 nm and 3 nm, only firms with large wafer volume see the cost per transistor fall[5]. It wrote that more companies will lack the volume to spread the fixed

cost of mask sets[5]. It expected failed chip designs to show up first among AI chip startups, which work on much tighter budgets[5].

Who makes it

Mask making splits between chipmakers that make masks for their own use and independent merchant firms that sell to them and others[1]. Photronics says that chipmakers' own shops once supplied most of the market, and that production has more recently tended to move toward the independents[1]. TSMC makes masks too, and lists mask making among the services it offers besides making wafers[33].

Photronics calls itself a leading worldwide maker of masks for chips and flat panel displays[10]. It had $849.3 million of revenue in fiscal 2025, $615.1 million of it from chip masks[10]. The competitors it names in chip and display masks include Dai Nippon Printing, Hoya, Tekscend Photomask and two Chinese firms, Shenzhen Newway Photomask and Shenzhen Qingyi Photomask[1]. It also competes with chipmakers' own mask shops[1].

SMIC, a Chinese foundry, runs two in-house mask shops in Shanghai that make masks for deep ultraviolet machines and older ones[12]. Photronics began operating two mask plants in China, in Hefei and Xiamen, in 2019[1]. Its chip mask business in Xiamen is a joint venture in which Dai Nippon Printing holds 49.99 percent[1]. No Chinese firm appears in CSET's 2025 market shares for electron-beam mask writers[2].

The chokepoint

Mask blanks are a small, highly concentrated business. In 2019 Lasertec launched the first tool that inspects patterned EUV masks in EUV light[9].

Pellicles already work in high-volume EUV manufacturing[29]. But ASML says no material is completely transparent to EUV light, so any pellicle in the light's path costs customers productivity[29]. In 2024 Mitsui Chemicals said it

would set up production of carbon nanotube membranes for next-generation High-NA, high-output EUV scanners[30].

FOUR QUESTIONS TO ANSWER FROM MEMORY

1. What is a photomask? see How it works
2. How many firms make the blank plates for EUV masks? see Blanks
3. Why is it hard for a new firm to enter the business? see The chokepoint
4. What masks can China make? see Who makes it

FOUR THINGS TO REMEMBER

- A photomask is the stencil for one layer of a chip, and any flaw on it repeats on every wafer.
- Three firms make EUV mask blanks, and Lasertec launched the first tool that checks finished masks in EUV light.
- AGC spent more than a decade learning to make EUV blanks before mass production began in 2017.
- China makes masks for deep ultraviolet machines and older ones, in SMIC's own mask shops and at independent firms such as Shenzhen Qingyi and Shenzhen Newway.
